FT-690R
6 METER PORTABLE TRANSCEIVER

INTRODUCTION

The FT-690R is a highly sophisticated, compact multi-mode transceiver for the 6 meter amateur band. Featuring PLL synthesis in 100 Hz, 1 kHz, 10 kHz, or 20 kHz steps, the FT-690R utilizes a Liquid Crystal Display for digital readout of the operating frequency. Ten memories, scanning of the band or memory channels, two VFOs, and receiver offset tuning make the FT-690R a significant breakthrough in technology.

Powered by eight "C" size dry cells or Ni-Cd batteries (not supplied), the FT-690R is completely self-contained and portable. A telescoping whip antenna is built into the FT-690R, for convenient portable operation. And a high-performance noise blanker is also included, for minimizing interference caused by impulse noise.

Power output is 2.5 watts (AM: 0.8W), switchable to 0.5 watt (AM: 0.2W) for battery conservation. For memory backup purposes, a lithium cell is included, providing an estimated lifetime of five years because of the extremely low current consumption of the memory circuitry. The light weight, portability, and efficiency of the FT-690R make it suitable for emergency FM work, or vacation enjoyment.

We recommend that you read this manual in its entirety, so as to understand more completely the many features of the exciting new FT-690R. With proper care in operation, this equipment will provide many years of reliable performance.

SPECIFICATIONS

GENERAL

Frequency coverage:
50 – 54 MHz
Modes of operation
SSB (USB), CW, AM and FM
Synthesizer steps:
SSB/CW/AM: 100 Hz, 1 kHz
FM: 10 kHz, 20 kHz

Power requirements:
8 x C - size dry battery cells or
8 x C - size Ni-Cd battery cells
External: 8.5 – 15.2 V DC
Memory backup: built-in lithium battery cell
Current consumption:
60mA on receive;
800mA on transmit (2.5W RF, FM)
Antenna impedance:
50 ohms
Case size:
58(H) x 150(W) x 195(D) mm
Weight:
1.3kg. without batteries

TRANSMITTER

Power output:
2.5 watts at 12 volts
(AM 0.8 watts)
Carrier suppression:
Better than 40 dB
Spurious radiation:
Better than 60 dB
Unwanted sideband suppression:
Better than 40 dB
Tone burst frequency:
1800 Hz
Frequency response:
300 – 2700 Hz (–6 dB)
FM deviation:
±5 kHz
Microphone impedance:
600 ohms

RECEIVER

Circuit type:
SSB/CW: Single conversion superheterodyne
AM/FM: Double conversion superheterodyne
Intermediate frequencies:
1st IF 10.81 MHz
2nd IF 455 kHz (AM/FM)
Sensitivity:
SSB/CW/AM: 0.5μV for 20 dB S/N
FM: 0.25μV for 12 dB SINAD
Selectivity:
SSB/CW: 2.4 kHz at 6 dB down;
4.1 kHz at 60 dB down
AM: 4 kHz at 6 dB down;
15 kHz at 60 dB down
FM: 14 kHz at 6 dB down;
25 kHz at 60 dB down
Image reduction:
Better than –60 dB
Audio output impedance:
8 ohms
Audio output:
1 watt @10% THD

Specifications subject to change without notice or obligation.

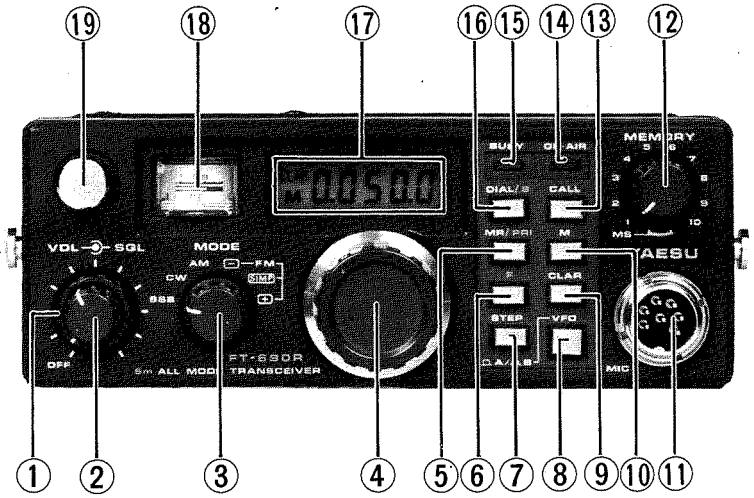
FRONT PANEL CONTROLS AND SWITCHES



(1) SQL

The squelch control silences the receiver in the FM mode when no stations are being received on the channel in use. The SQL control should only be advanced to the threshold point of background noise silencing; further advancement of this control will lead to reduced sensitivity to weak signals.

(2) VOL

This is the audio gain control for the receiver, as well as the main ON/OFF switch for the transceiver.

(3) MODE

This switch selects the desired mode: SSB (USB), CW, AM or FM.

(4) MAIN DIAL

The main tuning dial is used for selection of operating frequencies using the two main VFOs or the clarifier. In the SSB, CW, and AM modes, synthesizer steps of 100 Hz or 1 kHz are programmed, while on FM the channel steps are 10 kHz or 20 kHz each. In the clarifier mode, the synthesizer moves in 100 Hz steps.

(5) MR/PRI

This switch selects either the memory recall mode or priority channel operation. If only the MR/PRI switch is pressed, the memory channel selected by the MEMORY rotary switch will be activated. If the yellow F button is first pressed, then the MR/PRI button, priority channel operation will be selected.

(6) F

The yellow "F" (Function) button activates either the priority channel mode or the memory split mode. The F button itself does not select a mode, but it programs the microprocessor to select the mode labeled in yellow letters in either of the two switches immediately above the F button: DIAL/S or MR/PRI.

(7) STEP

This switch selects the desired synthesizer steps. In the SSB, CW, or AM mode, the preset mode is 1 kHz per step. Press the STEP button to switch to 100 Hz steps. A second press of this switch returns you to 1 kHz steps. In the FM mode, the preset is for 20 kHz steps. Pressing the STEP switch selects 10 kHz steps, while a second press returns you to 20 kHz steps.

(8) VFO Switch

The VFO button selects one of the two internal VFOs on the FT-690R. Upon switch-on, VFO-A is automatically selected. Press the VFO switch to select VFO-B, and dial up the new frequency. A second press of the button releases the switch, returning you to VFO-A.

(9) CLAR

This switch activates the receiver offset tuning feature (Clarifier). The clarifier allows ±10 kHz of offset from the transmit frequency, tuned in 100 Hz steps (all modes).

(10) M

The M (Memory) button is used to store a frequency in memory.

(11) MIC

This seven pin jack accepts microphone audio input, the scanning control lines, and the PTT (Push to Talk) control line. Microphone impedance is 500 ohms.

(12) MEMORY

The memory channel selector is used to choose any of the 10 memory channels. In the MS (Memory Scan) position, scanning of the memories may be performed.

(13) CALL

When this button is pressed (FM mode only), a 1800 Hz tone will be superimposed on the microphone line, and the PTT switch line will be grounded, activating the transmitter. This allows manual-length access of repeaters requiring a burst tone.

(14) ON AIR

This indicator lights up while you are transmitting.

(15) BUSY

This indicator lights up when the main squelch is opened up by an incoming signal.

(16) DIAL/S

When the DIAL/S button alone is pushed, tuning is accomplished by the main dial on either VFO-A or VFO-B. If the F button is pushed, then the DIAL/S button, the memory split mode will be selected, for receiving on the memory while transmitting on the VFO.

(17) DIGITAL DISPLAY

The digital display uses a liquid crystal display for indication of the operating frequency and mode. The frequency readout displays the last five digits of the operating frequency, with resolution to 0.1 kHz. Indicators are also provided for indication of clarifier operation ("CLAR"), memory channel operation ("M"), or memory split operation ("–" on transmit).

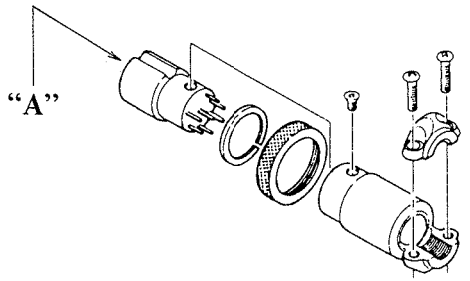
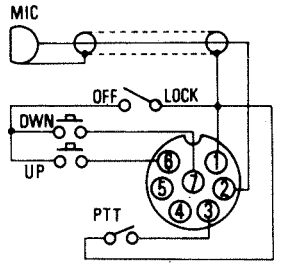
(18) S/PO

The meter allows determination of incoming signal strength and relative power output. The meter is also used for checking battery operation.

(19) WHIP ANTENNA

The built-in whip antenna is satisfactory for most portable operation. When using an external antenna, the whip should be telescoped fully into the transceiver. Conversely, when an external antenna is not used, the whip should always be fully extended.

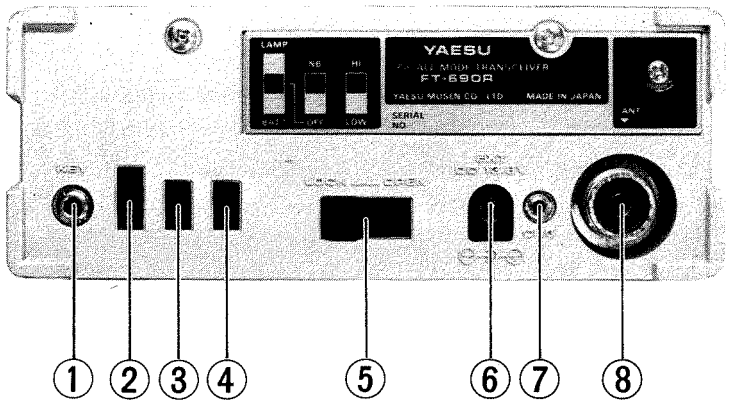




Viewed from "A" Side

YM-47
MICROPHONE PLUG CONNECTIONS

REAR APRON SWITCHES AND JACKS



(1) KEY

This jack is used for the keying input line. Use a miniature phone plug for connection to your telegraph key or keyer. The key-up voltage is 7V , and the key-down current is 0.3 mA.

(2) LAMP/BATT CHECK

With this switch in the LAMP mode, the front panel meter and LCD display will become illuminated for nighttime operation. If the power switch (on the VOL control) is off, this lamp will not come on, thus preventing inadvertent battery discharge.
In the BATT mode, the battery voltage is checked. The meter needle should deflect at least to the dividing line between the green and white zones of the meter scale. If not, the batteries will require recharging.

(3) NB

This switch activates the built-in noise blanker. While no blanker can be expected to eliminate all types of noise, such as white noise, etc., this blanker should prove highly effective in minimizing pulse-type noise such as that caused by automotive ignition systems.

(4) HI/LOW

This switch selects power outputs of 2.5 watts (HI) or 0.5 watt (LOW).

(5) CASE LATCH

This mechanism provides easy opening and closing of the cabinet for battery removal.

(6) EXT DC 13.8V

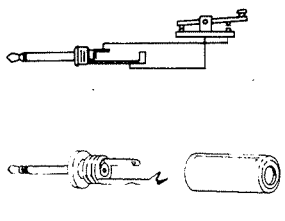
Use this jack for connection to an external DC supply. Never exceed 15 volts at this jack, and never apply AC power of any kind at this point. Also, be absolutely certain that DC power of the proper polarity is applied; when replacing DC plugs, check to be sure that the plug is wired correctly, as there is little standardization in the world for the power plug used for the FT-690R. Failure to observe these simple precautions will void any and all warranties on this equipment.

(7) CHG

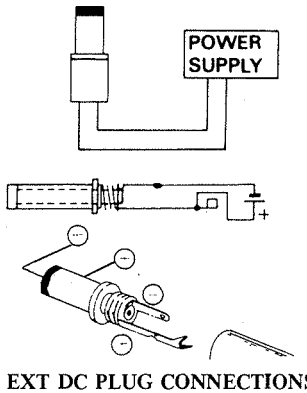
The external charge jack accepts charging voltage from the NC-11B/C battery charger (Option). When using alkaline or other dry cell batteries, do not attempt to recharge them. Use only C size Ni-Cd cells (available from your Yaesu dealer) if you desire rechargeable cells.

(8) ANT

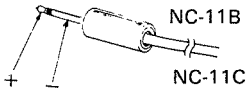
This is a UHF type connector for use with an external antenna of 50 ohms impedance (nominal). When using an external antenna, the internal whip should be telescoped fully inside the radio.



KEY PLUG CONNECTION

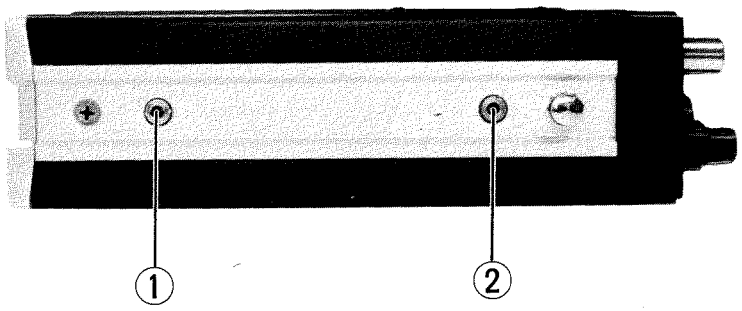


EXT DC PLUG CONNECTIONS



CHARGER PLUG CONNECTIONS

SIDE PANEL JACKS



(1) STAND BY

This jack is wired in parallel with the PTT line of the microphone, thus allowing the use of a footswitch to activate the transmitter.

(2) EXT SP

Use this jack for connection to an external speaker. The output impedance is 8 ohms.

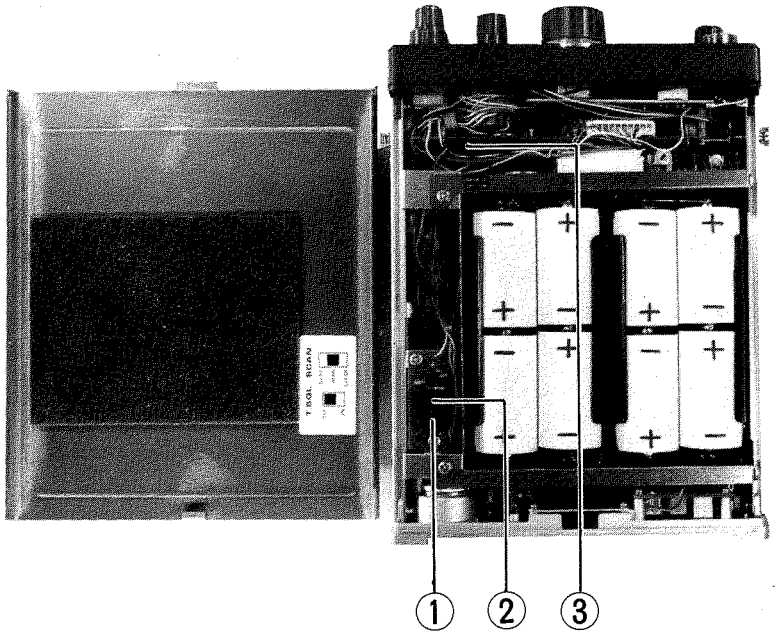
INTERNAL SWITCHES



(1) T SQL

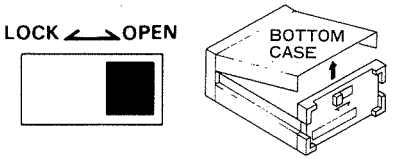
When the optional tone squelch unit is installed, this switch will place the unit in operation.

(2) SCAN

This switch selects scanning stop on a busy or clear channel, per your requirements. Manual scanning can also be selected, if desired.

(3) BACKUP

This switch activates the memory backup feature. Once the batteries are correctly installed, this switch may be turned on and left on indefinitely. See the operation section for details.



ANTENNA CONSIDERATIONS

The FT-690R is designed for use into a 50 ohm resistive load. While departures from this value are of no significant consequence, it is possible to damage the transmitter circuitry if no antenna is connected and the transmitter is activated.

For most portable use, the built-in telescoping whip antenna will provide satisfactory operation. For base station use, any of the popular beam or phased arrays will provide excellent performance, so long as they present the proper impedance to the transmitter and have been optimized for best forward gain.

When an external antenna is being used, the whip antenna should be telescoped fully into the FT-690R. Conversely, when no external antenna is connected, the whip should be fully extended. Failure to observe these simple precautions will void all warranties on this unit.

BATTERY INFORMATION

The FT-690R is designed for use with eight size C Ni-Cd rechargeable cells or eight dry cells of the same size. When using alkaline cells or other dry cell types, no "dummy" battery is required, as the FT-690R will tolerate the slightly elevated voltage of these batteries as compared to Ni-Cd cells.

To install batteries, set the rear panel lever to OPEN to unlock the case. The cabinet may then be carefully removed, exposing the battery holder. Install the eight new cells, being absolutely certain to observe the proper polarity.

WARNING

Serious damage can occur if incorrect battery polarity is used. Our warranty does not cover damage caused by incorrect polarity in the battery compartment.

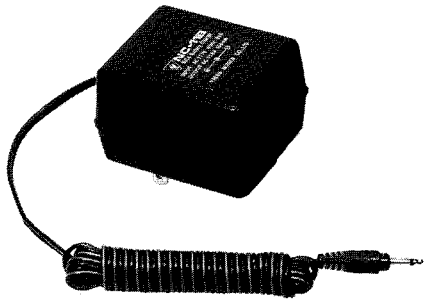
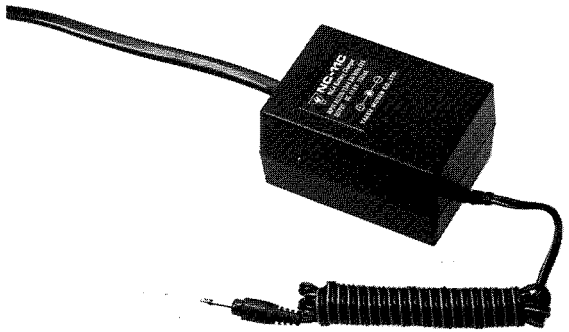
If Ni-Cd cells are used, the optional NC-11B/C battery charger may be used to return the cells to a full charge. Always be certain that cells are allowed to discharge fully before recharging them. If the cells are only partially exhausted, and repeatedly recharged in this condition, they may develop a memory for this level, and not provide full discharge capability.

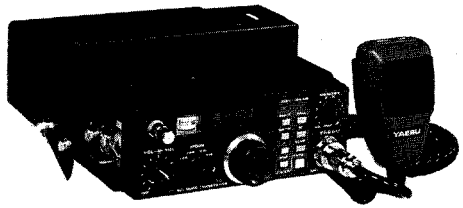
Ni-Cd cells suitable for use in the FT-690R are available from your Yaesu dealer. Ask also for the MMB-11 Mobile Mounting Bracket and CSC-1 vinyl carrying case for the FT-690R.



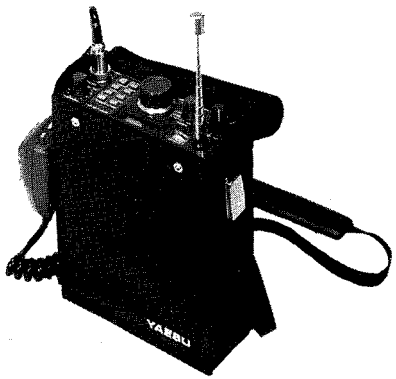
NC-11B (117V AC)



NC-11C (220 – 234V AC)



FT-690R/MMB-11/YM-47



FT-690R/CSC-1/YM-47

OPERATION

The tuning procedure for this transceiver is not complicated. However, because microcomputer circuitry is used extensively throughout the transceiver, this section should be read thoroughly, so as to understand all of the features that are made available. Note that off-frequency operation could occur without proper setting of the controls, because of the many options the operator has for frequency selection.

INITIAL CHECK

Before operating the transceiver, be certain that the necessary batteries are installed in the case, as described previously. Extend fully the built-in telescoping whip antenna, if used. If an external antenna is used, be certain that the internal whip antenna is fully nested into the FT-690R. If an external voltage source is used instead of batteries, confirm that the proper DC voltage is being applied to the rear panel jack, and that the proper polarity is used.

FREQUENCY READOUT

Frequency display is provided by way of a five-digit Liquid Crystal Display (LCD) system. Resolution of the last five digits of the operating frequency is provided to 0.1 kHz.

When operating on a memory channel, the letter "M" will appear on the left side of the display. The memory channel number will not be shown, as it is already shown on the selector switch labeling. The actual memorized frequency will be displayed, however.

SSB/AM OPERATION

Preset the controls and switches as follows:

VOL		OFF (Fully counterclockwise)
SQL		Fully counterclockwise
MODE		Desired mode, SSB (USB) or AM
MEMORY		Channel 1
LAMP	(Rear apron)	OFF
NB	(" ")	OFF
HI/LOW	(" ")	HI

Rotate the VOL switch out of the click-stop, and adjust the volume level for a comfortable audio output from the speaker. The LCD display will indicate the operating frequency. Initially (first switch-on after the memory backup battery has been installed), the display will indicate "0.000.0" (50.000.0 MHz) as a preset frequency; thereafter, when the transceiver is switched on, the backup feature will keep you locked onto the frequency and mode (dial or memory) last used when you switched the unit off.

The STEP switch is used to select the desired synthesizer step, 1 kHz or 100 Hz per step (SSB/CW/AM modes). If you rotate the main tuning dial, initially the synthesizer will provide 1 kHz steps. Press the STEP button once, and you will note that the steps are now 100 Hz (0.1 kHz) each. Another pressing of the STEP button will return the selection to 1 kHz/step.

Rotate the main tuning dial until an SSB signal is heard. Using the 100 Hz/step mode, tune in the signal until a natural reproduction of the voice signal is obtained.

To transmit, close the microphone PTT switch, and speak at a normal level into the microphone. Release the PTT switch for receiver recovery. The microphone amplifier gain is preset in this transceiver, and it requires no further adjustment for normal operation.

If the station you are in contact with suddenly begins to drift, you may follow the drifting station by activating the receiver offset tuning control (CLARIFIER). Push the CLAR button, and then rotate the main tuning dial (or push the scanning controls) until the desired frequency is reached. In the CLAR mode, the synthesizer is automatically set to the 100 Hz step mode, and the STEP button is disabled. The clarifier leaves the transmit frequency unchanged.

Push the CLAR button again to return to normal operation with the clarifier off. If you switch the clarifier on again, the receiver will **not** return to the last offset frequency, but rather will initiate on the current operating frequency.

If pulse-type noise is encountered, the rear apron NB (Noise Blanker) switch may be activated. While no noise blanker can be expected to eliminate all types of atmospheric and man-made noise encountered in day-to-day operation, the FT-690R noise blanker should be quite helpful in reducing interference caused by pulse noise such as that produced by automobile ignition systems.

To reduce power for local communication, place the HI/LOW power switch in the LOW position. In this position, the PEP output power is approximately 500 mW (AM: 200 mW). Battery consumption will be greatly reduced by using the low power position whenever possible.

FM OPERATION

Preset the controls and switches as described for SSB operation, but set the MODE switch to FM/SIMP.

In the FM mode, the synthesizer steps provided are 10 kHz and 20 kHz per step (the clarifier steps are still 100 Hz/step). When you are changing modes from SSB to FM, and were last operating on other than a 10 kHz or 20 kHz step, the microprocessor will automatically move you to the next higher or lower 10 kHz or 20 kHz step upon the first click of the main tuning dial (or first stepping of the scanner).

Rotate the main tuning dial (or operate the scanning controls) until the desired frequency is reached. To transmit, close the PTT switch, and speak into the microphone in a normal voice. Release the PTT switch for receiver recovery.

For repeater operation, selection of the standard ±1 MHz splits is provided on the front panel. For −1 MHz shift, set the MODE switch to FM/−, and for +1 MHz shift, select FM/+. This selection can be made either during main dial or memory operation.

For operation on odd splits, use a combination of the memory system and the main tuning dial. First, store the desired receive frequency in any memory channel. Now use the main dial to select the desired transmit frequency. Next push the yellow F and S buttons. You will now be receiving on the memory channel just programmed. When you close the PTT switch, you will be transmitting on the main dial frequency. If you desire to listen on several memory channels, the memory channel selector may be rotated as desired.

The front panel CALL switch activates a manual-length 1800 Hz tone for repeater access. When this button is pushed, the transmitter is activated and the access tone is superimposed on the transmit signal.

Rotate the SQL (Squelch) control fully counterclockwise. Now turn the VOL control out of the click-stop to turn the transceiver on. Advance the volume control for a comfortable listening level.

When the channel is clear, adjust the SQL control so the background noise just disappears. This threshold point is the point of maximum sensitivity, and the squelch control should not be advanced beyond this point too far, or the squelch will not respond to weak signals.

CW OPERATION

(1) The synthesizer steps selected in the CW mode are identical to those used for SSB operation.

(2) Connect a key to the rear panel KEY jack, using a miniature phone plug. The key-up voltage is 7V, while the key-down current is 0.3mA, so most electronic keyers that close completely to ground will work well with the FT-690R.

(3) Set the MODE switch to CW.

(4) Close the PTT switch on the microphone to switch to the transmit mode. If desired, a footswitch may be used with the FT-690R. The STAND BY jack, located on the side of the transceiver, is wired in parallel with the PTT line on the microphone. This may be used in situations where the microphone is not the most efficient means of activating the transmitter.

(5) The clarifier may be used for following unstable signals. The clarifier allows offset tuning in 100 Hz steps away from the transmit frequency. See the section on clarifier operation for details.

CLARIFIER OPERATION

Offset tuning is provided on receive, for tracking of unstable or Doppler-shifted signals. The clarifier may be used either on VFO frequencies or memory frequencies.

To activate the clarifier, push the CLAR button once. The letters "CLAR" will appear on the digital display. Now, tune the receiver as needed to follow the unstable signal. The synthesizer automatically programs 100 Hz steps for clarifier operation. A frequency shift of up to 10 kHz can be accomplished by using the clarifier.

When you close the PTT switch, the digital display will revert to the frequency programmed **before** the clarifier was switched on. In other words, your transmit frequency has remained unchanged, while your receive frequency has been varied.

A second press of the CLAR button will cancel clarifier operation. If the CLAR button is then pressed again, switching the clarifier back on, the clarifier is zeroed to the original operating frequency (before any offset), **not** to the offset frequency programmed previously.

THE UP/DWN CONTROLS ON THE MICROPHONE MAY BE USED FOR SCANNING DURING CLARIFIER OPERATION.

VFO SELECTION

Two VFOs are available on the FT-690R for split frequency operation. The VFO selector button is the largest of the eight mode selector buttons on the front panel of the FT-690R. This switch is a push-push type, not the momentary type used for the other mode selector buttons.

For VFO B operation, push the VFO button once; the switch will hold inward, and the desired frequency may then be dialed up. Be certain, of course, that you are in the DIAL mode. To return to VFO A, simply push the VFO button again to release the switch.

It is not possible to receive on one VFO while transmitting on another. For frequency splits of 10 kHz or less, use the clarifier to achieve this function. Otherwise, use the MEMORY SPLIT mode described elsewhere in this manual.

NOTE REGARDING BACKUP OPERATION

When a backup battery or main batteries are first installed in the FT-690R (after service or replacement), it is necessary to reset the microcomputer properly. Failure to follow a simple sequence of steps may cause erratic operation.

(1) Set both the VOL and memory backup switches (memory backup switch is located inside the cabinet, as shown on page 11) to OFF.

(2) Replace the memory backup battery and main batteries (if removed).

(3) Turn the VOL control out of the click-stop, turning the transceiver ON.

(4) Now turn the backup switch to ON. The CPU is now reset, and the backup switch may be left on indefinitely, owing to the very low current drain in the backup mode.

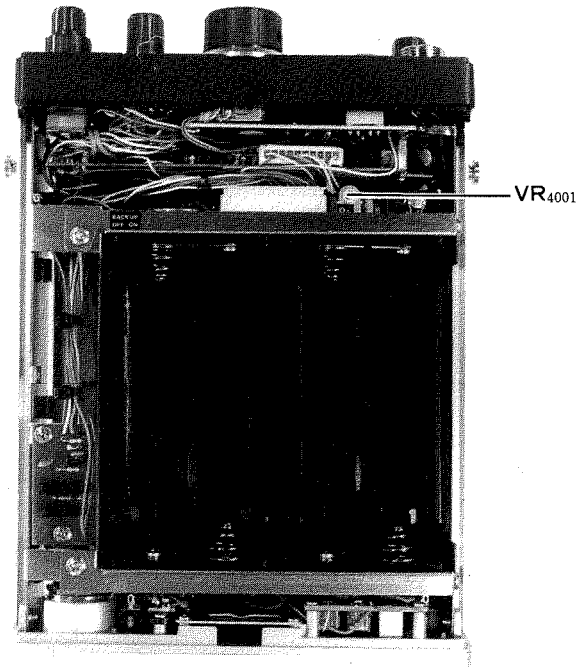
(b) Set the MODE switch to FM and close the PTT switch. Adjust VR_{2007} so that a minimum spurious level appears ±10.81 MHz from the carrier on the spectrum analyzer.

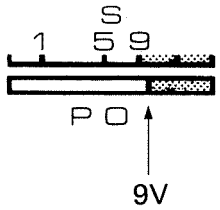
12. Battery Check

(a) Apply DC 9V to the EXT DC 13.8V terminal from an external power supply.

(b) Set the LAMP/BATT CHECK switch (on the REAR PANEL) to the BATT CHECK position.

(c) Adjust VR_{4001} so that the PO meter deflects to the left side of the green zone.





8. SSB Carrier Point Adjustment

(a) Apply a 1 kHz 2 mV signal from the audio generator to the MIC jack and adjust VR_{2001} for an output of 2.5 watts.

(b) Set the MODE switch to SSB and the frequency of the audio generator to 300 Hz. Adjust TC_{1002} for an output of 0.6 watts.

9. Carrier Balance Adjustment

(a) Temporarily short the PTT line at the MIC jack, using a jumper wire, not the microphone.

(b) Monitor the carrier on a monitor receiver, and adjust VR_{1001} for minimum S-meter reading (or minimum signal level if no S-meter reading occurs).

10. CW Carrier Frequency Adjustment

(a) Set the MODE switch to CW.

(b) Connect a frequency counter to the cathode of D_{2017}.

(c) Connect a CW key to the KEY jack, and then close the PTT switch and KEY simultaneously. Adjust TC_{1003} for a frequency of exactly 10.8107 MHz.

(d) Now set the frequency to 52.100.1 MHz and place the input lead from the counter to the dummy load to read the transmit frequency. Then adjust L_{3007} for a reading of 52.100.0 MHz ±100 Hz on the frequency counter.

11. TX Balanced Mixer Alignment

If you do not have a spectrum analyzer, do not perform this alignment, as serious spurious radiation will result.

(a) Connect a directional coupler between the transceiver and dummy load/wattmeter, and feed the coupled output from the directional coupler to the spectrum analyzer.

MEMORY OPERATION

Ten memory channels are available for storage and recall of favorite operating frequencies. The procedure for entry and recall of memory channels is extremely simple.

Push the DIAL switch for normal tuning, using the main tuning dial. When you have found a frequency you wish to store in memory (for example 50.520 MHz), rotate the MEMORY switch to 1 (channel 1) and push the M (memory store) button. If you wish to store 50.490 MHz in channel 2, rotate the main dial to that frequency, rotate the MEMORY switch to channel 2, and push M, and so forth. This procedure may be repeated for all 10 memory channels.

To recall these frequencies, push the MR button (memory recall) and rotate the MEMORY switch to select the desired channel. One push of the M button will keep you on memory recall operation until the DIAL button is pushed again to return you to main dial tuning. Note that there is no formal erasure procedure for memory channels. When you push the M button, the previous frequency stored in that position will be erased. Until a frequency is programmed into a memory channel (from initial switch on of the transceiver), 50.000 MHz will be preset in all memory channels.

SCANNER OPERATION

The UP/DOWN scanning controls on the microphone may be used to control the operating frequency.

When in the DIAL mode, one push of the UP button will cause the frequency to advance upward by one step of the synthesizer (the step size being programmed by the mode switch and the STEP button). If you hold the UP button down for more than 1/2 second, the scanner will become engaged, and you will begin scanning up the band. Push the UP or DN button or the PTT switch to halt the scan.

Scanning toward a lower frequency is achieved by using the same procedure, only using the DN button on the microphone.

To scan only the memory channels, rotate the MEMORY selector to either of the MS (Memory Scan) positions, and press the MR button. Now, when you push and hold the UP or DN button, the scanner will search the memory channels only. Manual halting of the scan is accomplished by pushing the UP, DN, or PTT switches as before.

Inside the case of the radio, the BUSY-MAN-CLEAR switch allows selection of one of three scan halt modes. In the MAN (Manual) position, scanning is halted as discussed above. If the BUSY position is selected (see Page 11), the scanner will search until a busy channel (one occupied by a station strong enough to break the main squelch) is received. The scan will then pause on that frequency for five seconds. If you choose to stay on that frequency, press one of the scan control buttons or the PTT switch. While in the PAUSE mode, the decimal point farthest to the right will blink; when you push a button to halt the resumption of the scan, the blinking will stop.

To scan for a clear channel (one where the squelch does not open), set the BUSY-MAN-CLEAR switch to CLEAR. The scan will halt, and the decimal point will blink, as in the previous section. Press the UP, DN, or PTT switch to cancel the pause/resume feature and hold on the frequency you stopped at.

Memory scan halting follows the same format as main dial scanning.

PRIORITY CHANNEL OPERATION

Priority channel operation uses a combination of the main dial VFO and the memory. It can be used in conjunction to the automatic scan stop feature of the microprocessor, if desired. The steps for priority channel operation are detailed below.

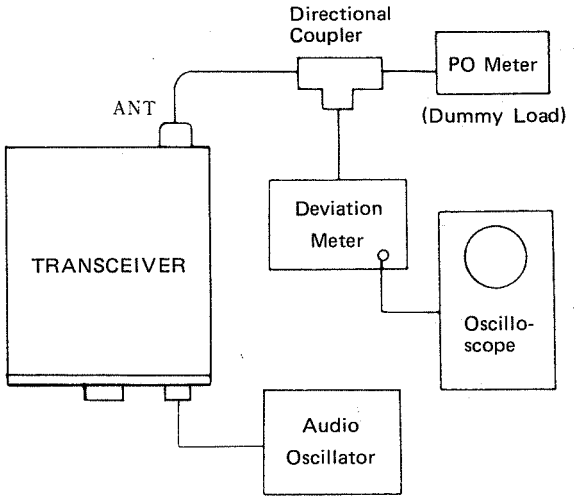


Figure 2

(c) Now close the PTT switch, and adjust VR_{2002} for a deviation of ±4.5 kHz while observing the signal waveform on the scope.

(d) Reduce the amplitude of the audio generator to 2 mV, and check to see that the linear detector shows ±3.5 kHz and that the signal waveform on the scope is not distorted.

5. AM Modulator Adjustment

(a) Set the MODE switch to AM.

(b) Adjust VR_{2005} for an output of 0.8 watts without modulation.

6. Low Power Adjustment

(a) With the dummy load/wattmeter connected to the ANT jack, set the MODE switch to FM and the HI/LOW switch to the LOW position.

(b) Close the PTT switch and adjust VR_{2006} for an output of 0.5 watts.

7. SSB Modulator Output Transformer Adjustment

(a) With a dummy load/wattmeter connected to the ANT jack, set the MODE switch to SSB.

(b) Set VR_{2001} to the center of its range and apply a 1 kHz 2 mV signal from the audio generator to the MIC jack.

(c) Adjust T_{1012} for maximum power output.

TRANSMITTER

The transmitter alignment should be performed with a dummy load connected to the antenna jack.

1. RF Power Stage Alignment

(a) Tune the transceiver to 52.000 MHz, and set the MODE switch to FM. Connect a dummy load/wattmeter to the ANT jack.

(b) Rotate VR_{2003} and VR_{2004} fully counterclockwise, and close the PTT switch.

(c) Connect the RF probe of a VTVM to the cathode of D_{3003} and check to see that the VTVM shows approximately 500 mV rms.

(d) Connect the RF probe of the VTVM to the cathode of D_{2017} and a frequency counter to the same point.

(e) Adjust the core of L_{2002} for a reading of 10.81 MHz ±100 Hz, and be sure its level is approximately 500 mV rms.

(f) Now adjust T_{2001} – T_{2003}, T_{2005}, T_{3001}, TC_{2004} and TC_{2005} for maximum reading on the wattmeter.

2. ALC Alignment

(a) Set the MODE switch to FM, and close the PTT switch.

(b) Adjust VR_{2003} for a reading of 2.5 watts on the wattmeter.

3. PO Meter Alignment

(a) Set the MODE switch to FM and close the PTT switch.

(b) Adjust VR_{2004} so that the PO meter indicator reaches the middle of the green zone, with a 2.5 watt reading on the wattmeter.

4. FM Deviation Alignment

(a) Assemble the test equipment and the transceiver as shown in Figure 2.

(b) Connect an audio generator to the MIC jack, and apply a 1 kHz 15 mV signal.

(1) Program into memory the desired priority channel. Do not **recall** the channel at this time.

(2) Dial up a basic operating frequency on the main VFO. This will be your main operation channel during priority channel operation.

(3) Set the BUSY-MAN-CLEAR switch to BUSY or CLEAR, as desired.

(4) Now push the yellow F button, followed immediately by a press of the MR/PRI button. The letter "P" will appear on the digital display, signifying priority channel operation. The display will then show the VFO frequency, with a flash every five seconds to the memory channel being checked for activity. When the memory channel is busy or clear (depending on your instructions), the scanner will halt on the memory channel. The pause/restart feature does not function in this mode; to restart, simply press the F and MR/PRI buttons again.

(5) If the scan stop switch is set to the MAN position, the CPU will have no instructions for halting the scan. Simply press the DIAL or MR button to select the desired channel under this mode of operation. If you hit the PTT switch during manual priority channel operation, the checking of the priority channel will be delayed by five seconds.

MEMORY SPLIT OPERATION

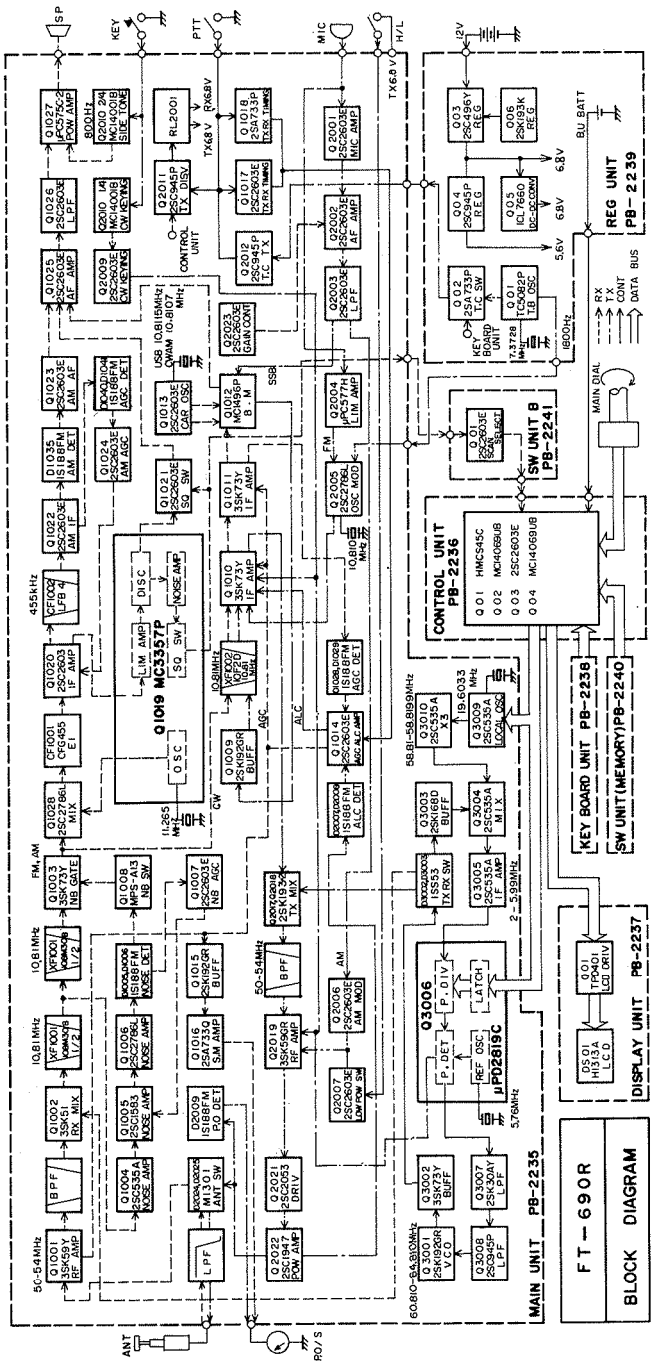
The memory split operation mode is useful for covering unusual repeater splits or other occasions where the receive frequency may be fixed, but the transmit frequency is variable. In this mode, you receive on a memory channel, while transmitting on the VFO.

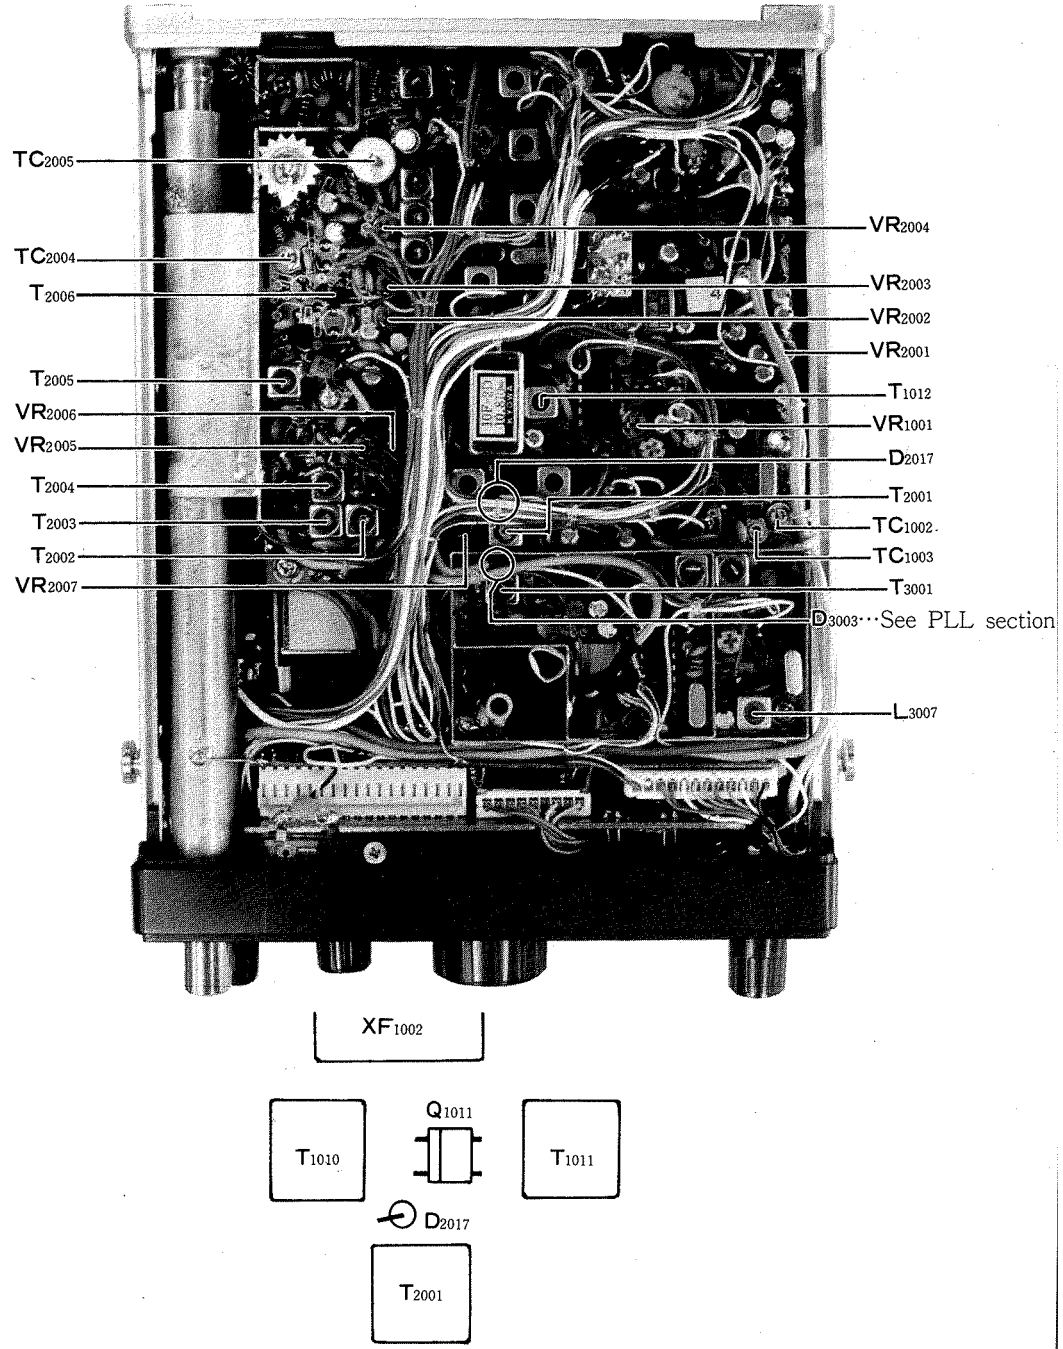
(1) Store the desired receive frequency into a memory channel.

(2) Dial up the desired transmit frequency on the main dial.

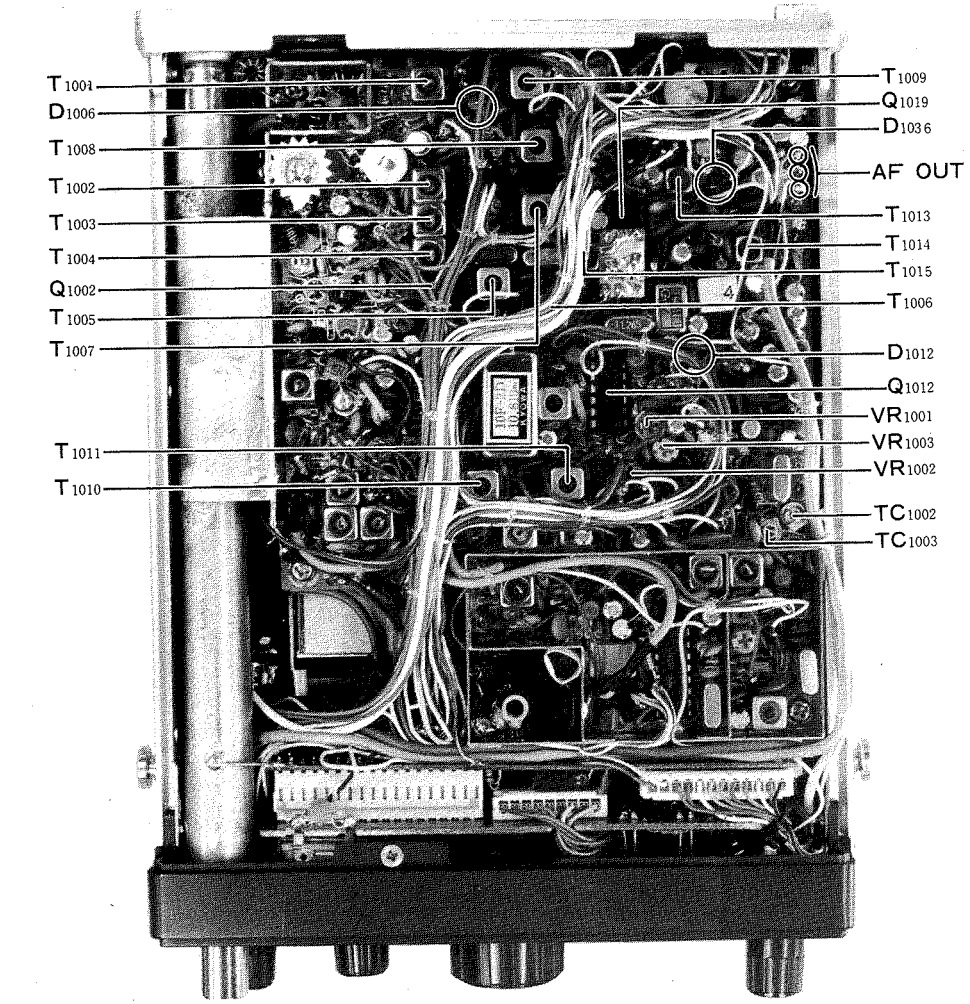
(3) Now press the yellow F and DIAL/S buttons. You will be receiving on the memory, while transmitting on the VFO.

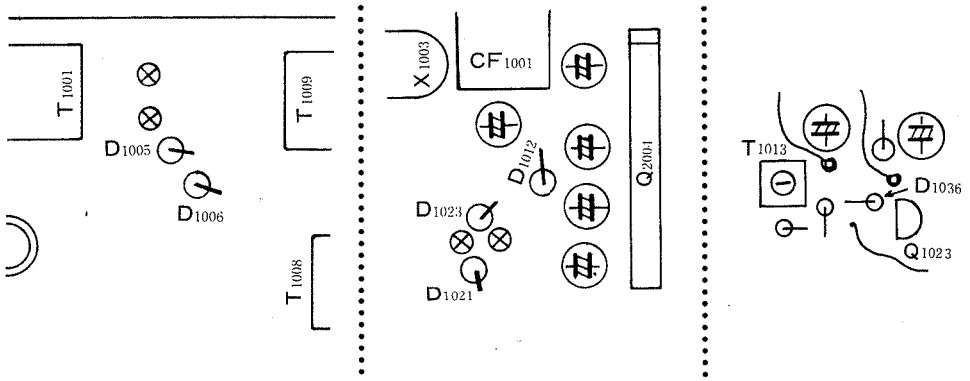
(4) For transmitting purposes, either VFO A or VFO B may be used. Set the VFO selector as needed.





TRANSMITTER SECTION ALIGNMENT POINTS





RECEIVER SECTION ALIGNMENT POINTS

CIRCUIT DESCRIPTION

The block diagram and circuit description to follow will provide you with a better understanding of this transceiver. Please refer to the block and schematic diagrams for specific circuit details.

RECEIVER

The RF signal from the antenna jack is applied to a lowpass filter and diode antenna switch, consisting of D_{2024} and D_{2025} **(MI301)** and is then fed to an RF amplifier, Q_{1001} **(3SK59Y)**, where the signal is amplified with excellent rejection of cross modulation and intermodulation. The amplified signal is then fed through three sections of Auto-tuning filter to reject unwanted signals which may cause intermodulation at the 1st Mixer, Q_{1002} **(3SK51-03)**. Here, the signal is mixed with a local signal delivered from the local oscillator buffer, resulting in a 10.81 MHz first IF signal.

The first IF signal passes through a pair of monolithic crystal filters, XF_{1001} **(108M30B)**, which have bandwidths of ±15 kHz. It is then amplified by Q_{1003} **(3SK73Y)**, which acts as a switch, driven by the NB (noise blanker) circuit. The amplified signal from Q_{1003} is fed to IF amplifiers for FM/AM or SSB/CW.

A portion of the RF signal from monolithic crystal filter XF_{1001} is fed to a noise blanker amplifier circuit, consisting of Q_{1004} **(2SC535A)**, Q_{1005} **(2SC1583)** and Q_{1006} **(2SC2786L)**, where the signal is amplified to a level sufficient to drive the noise blanker rectifier and noise blanker AGC circuits.

When the carrier of a noise-free modulated signal is received, the signal at the noise amplifier is rectified by D_{1005} and D_{1006} **(1S188FM)**, producing a DC voltage. The DC voltage is amplified by Q_{1007} **(2SC2603E)**, which charges C_{1042} for AGC purposes. The AGC voltage is used to control the gain of Q_{1005} and Q_{1006}.

When a pulse-type noise is received, D_{1005} and D_{1006} rectify the noise, and it is then fed through D_{1044} **(1S188FM)** to a DC amplifier, Q_{1008} **(MPSA13)**, which drives gate 2 of Q_{1003}.

The FM/AM mode signals are fed to mixer Q_{1028} **(2SC2786L)**, where they are heterodyned with an 11.265 MHz local signal delivered from the oscillator section of Q_{1019} **(MC3357P)**, resulting in a 455 kHz FM/AM IF signal.

This signal then passes through ceramic filter CF_{1001} and is amplified by Q_{1020} **(2SC2603E)** for the FM and AM IF amplifiers.

The FM mode signal is delivered to the IF amplifier/limiter section of Q_{1019}, where the IF signal is amplified, and any amplitude modulation in the signal is rejected. Then, the signal is delivered to the discriminator section, which produces an audio output in response to a corresponding shift in the 455 kHz IF signal.

When no carrier is present in the 455 kHz IF, the high frequency noise at the discriminator output, which passes through a bandpass filter, is amplified by the noise amplifier in Q_{1019} and detected by D_{1032} **(1S188FM)**, producing a DC voltage. This voltage activates a switch in Q_{1019} which grounds the base of Q_{1021} **(2SC2603E)**, to turn off the AF output from the discriminator to the AF amplifier.

When a carrier is present in the 455 kHz IF, the noise is removed from the discriminator and the audio amplifier then returns to normal operation. The squelch threshold sensitivity is set by VR_{1b}.

The 455 kHz AM IF signal from Q_{1020} is fed through a ceramic filter, CF_{1002} to AM IF amplifier Q_{1022} **(2SC2603E)**. This amplified signal is then detected by a diode AM detector, D_{1035} **(1S188FM)**, producing an AF signal. It is then amplified by Q_{1023} **(2SC2603E)** for the AF amplifier.

SSB and CW mode IF signals from Q_{1003} are passed through a crystal filter, XF_{1002}, which has a very high shape factor, to reduce signals on adjacent frequencies. The filtered SSB signal is amplified by Q_{1010} and Q_{1011} **(3SK73Y)**, and then fed to the balanced demodulator, Q_{1012} **(MC1496P)**,

4. AM IF Alignment

(a) Set the MODE switch to AM and the frequency to 52 MHz.
(b) Connect an RF signal generator to the ANT jack and set the output level and frequency to 15 dBμ at 52 MHz (1 kHz, 30% modulated).
(c) Connect an oscilloscope to D_{1036}, and adjust the core of T_{1014} for maximum amplitude on the scope.

5. RF Coil Alignment

(a) Set the output level and frequency of the generator to 10 dBμ at 52 MHz.
(b) Set the receiver frequency to 52 MHz, and adjust the cores of T_{1001} – T_{1004} for maximum deflection on the S-meter.

6. S-meter Alignment

(a) Set the MODE switch to SSB and preset VR_{1001} to the center position.
(b) Apply a 16 dBμ signal from the signal generator, and adjust VR_{1003} for a reading of S9 on the S-meter.
(c) Now remove the signal from the signal generator, and adjust VR_{1002} so the S-meter indicates exactly 0.
(d) Repeat steps (b) and (c) a few times to obtain the proper S-meter deflection.

7. N.B. Alignment

(a) Set the MODE switch to CW and apply a 5 dBμ signal from the signal generator.
(b) Connect the ⊕ lead of a DC voltmeter to the cathode of D_{1006} and the ⊖ lead to the −6.8 volts line.
(c) Adjust the cores of T_{1007} – T_{1009} for maximum deflection on the voltmeter.
(d) Next, reduce the amplitude of the signal generator to 0 dBμ, and check the voltmeter, which should show approximately 0.03 volts.

RECEIVER ALIGNMENT

1. First IF Alignment

(a) Set the MODE switch to FM.

(b) Connect a sweep generator output to gate 1 of Q_{1002} and set the frequency of the sweep generator to 10.81 MHz.
Connect an oscilloscope, through a detector, to pin 16 of Q_{1019}.

(c) Adjust the cores of T_{1005}, T_{1006} and T_{1015} until the scope pattern illustrated in Figure 1 is obtained.

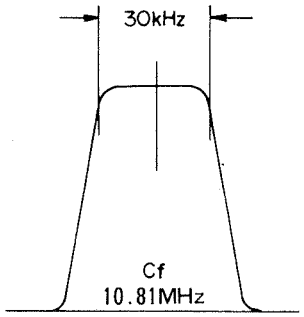


Figure 1

2. FM Discriminator Alignment

(a) Set the MODE switch to FM and the SQL control fully counterclockwise.

(b) Connect an audio voltmeter to the speaker terminal.

(c) Set the VOL control to the center position, and adjust the core of T_{1013} for a maximum reading on the meter.

3. SSB/CW IF Alignment

(a) Set the MODE switch to CW and the frequency to 52 MHz.

(b) Connect an RF signal generator to the ANT jack and set the output level and frequency to 15 dBμ at 52 MHz.

(c) Adjust the cores of T_{1006}, T_{1010} and T_{1011} for maximum reading on the S-meter.

where a carrier signal is applied from carrier oscillator Q_{1013} **(2SC2603E)**, resulting in an AF signal, which is then fed to the AF amplifier.

The AF amplifier consists of Q_{1025}, Q_{1026} **(2SC2603E)** and Q_{1027} **(μPC575C-2)**. The AF signal from the FM discriminator and the balanced demodulator are amplified by Q_{1025}, and fed to active lowpass filter Q_{1026}, where the AF signal above 3 kHz is cut off. The AF signal is then delivered to AF power amplifier Q_{1027}, providing approximately 1 watt of audio output to the speaker.

S-METER AND AGC CIRCUITS

A portion of the IF signal from Q_{1011} is rectified by D_{1028} and D_{1029} **(1S188FM)** and amplified by Q_{1014} **(2SC2603E)**. This amplified DC voltage controls gate 2 of MOS FET's in the IF amplifier. A portion of the AGC signal is buffered by Q_{1015} **(2SK192GR)**, and fed to the S-meter amplifier, Q_{1016} **(2SA733Q)**, providing a DC voltage for the S-meter deflection.

TRANSMITTER

The discussion of the signal flow on transmit will be made on a mode-by-mode basis.

SSB

The audio input signal from the microphone is amplified by Q_{2001} and Q_{2002} **(2SC2603E)**, and then delivered to an active lowpass filter, Q_{2003} **(2SC2603E)**, where the unwanted frequency spectrum above 3 kHz is cut off. This amplified speech signal is fed to balanced modulator Q_{1012} **(MC1496P)**, where the audio signal modulates the 10.8115 MHz carrier signal delivered from the carrier oscillator, Q_{1013} **(2SC2603E)**, resulting in a 10.81 MHz double-sideband signal. The DSB signal is amplified by a buffer, Q_{1009} **(2SK192GR)**, and delivered to crystal filter XF_{1002} **(10F2D)**, where the unwanted sideband is sliced out, resulting in a single sideband signal. This SSB signal is then amplified by Q_{1010} **(3SK73Y)**, and delivered to a mixer, Q_{2017} and Q_{2018} **(2SK193F)**, where the SSB signal is mixed with a local signal from the PLL local oscillator buffer, Q_{3002} **(3SK73Y)**, resulting in a 50 – 54 MHz SSB signal.

The SSB signal passes through an auto-tuning filter consisting of T_{1002}, T_{1003}, T_{1005} and varactor diode D_{1018}, D_{1019}, D_{1021} **(1SV69)**, where the resonant frequency is tuned exactly to the transmitting frequency, thus minimizing spurious radiation. The signal is then amplified by three stages of straight amplifier consisting of Q_{2019} **(3SK59GR)**, Q_{2021} **(2SC2053)** and Q_{2022} **(2SC1947)**, providing a power output of 2.5 watts over the range of 50 – 54 MHz.

Finally, this signal passes through an RF diode switch and lowpass filter to the ANT connector and built-in telescoping antenna.

FM

The speech signal from the microphone is amplified and limited in amplitude by Q_{2004} **(μPC577H)**. It is then fed through a lowpass filter to eliminate harmonics above the speech range, caused by clipping. Next it goes to a frequency modulator consisting of Q_{2005} **(2SC2786L)** and D_{1005} **(1SV68)**, where the 10.81 MHz oscillating frequency is modulated, corresponding to the AF signal from Q_{2004}. Thus, an FM signal of 10.81 MHz is produced. This signal is then delivered to the IF amplifier, Q_{1010}, and the signal path then becomes identical to that of the SSB signal.

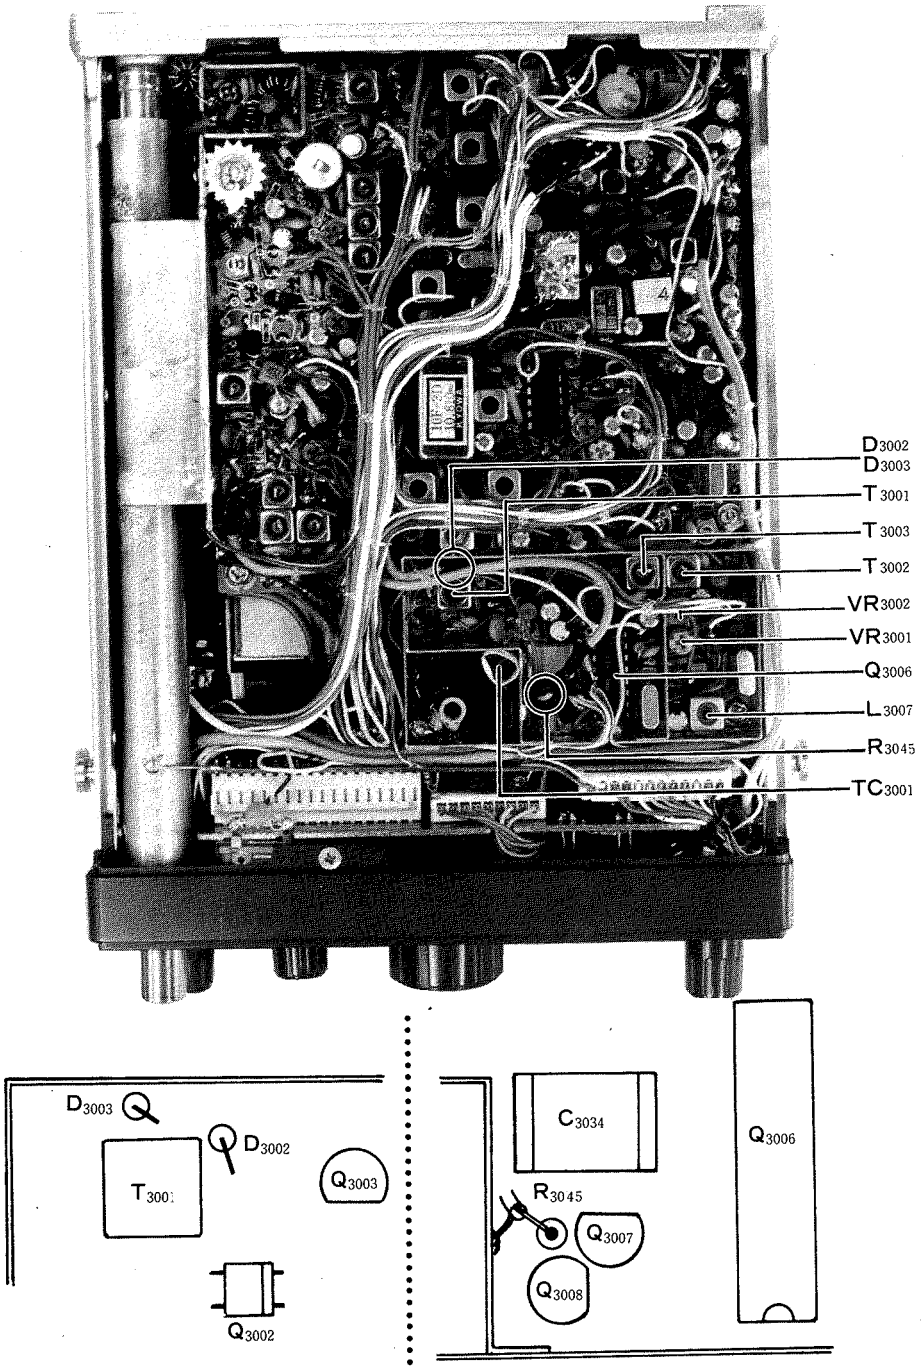
CW/AM

For CW, the 10.8107 MHz carrier is generated by Q_{1013} **(2SC2603E)**, and delivered to the balanced modulator Q_{1012}. The key line is connected to keying control IC (quad NOR gate) Q_{2010} **(MC14001B)**, which drives keying switch Q_{2009} **(2SC2603E)** to control the DC bias voltage sent to the source of Q_{1010} and Q_{2019}. As a result, the RF signal is turned on and off.

From this point, the signal path is identical to that of the SSB signal.

The control signal from Q_{2010} is also fed to the sidetone oscillator consisting of two sections of gate circuits in Q_{2010}, which oscillate sidetones of about 800 Hz and the sidetone signal is then delivered to the AF amplifier.

During AM operation, the amplified speech signal from Q_{2003} is amplified by another amplifier, Q_{2006} **(2SC2603E)**, and the output signal controls the voltage at gate 2 of Q_{2019}. Thus, the CW carrier signal is modulated and delivered to the driver/final amplifier section.



PLL SECTION ALIGNMENT POINTS

PLL CIRCUIT ALIGNMENT

The PLL circuit alignment procedure is very critical because of the ambient temperature change. This alignment must be performed under temperature conditions between the range of 15 to 30°C. If your transceiver is exposed to temperatures beyond this range for an extended period of time, the transceiver should sit in the proper alignment temperature for at least two hours before you start the following alignment procedure.

1. PLL Local, IF Alignment

(a) Set the MODE switch to the FM position, and adjust the frequency to 52.000.0 MHz.
(b) Set TC_{3001} to the center position, and connect an oscilloscope to pin 14 of Q_{3006}.
(c) Adjust the cores of T_{3001} – T_{3003} for maximum amplitude on the oscilloscope.

2. VCV Line Adjustment

(a) Tune the transceiver to 54.000.0 MHz, and connect a DC voltmeter to R_{3045}.
(b) Adjust TC_{3001} for a reading of 5.5 volts on the meter.

3. PLL Local Frequency Adjustment

(a) Set the MODE switch to FM and tune the transceiver to 52.000.0 MHz. Preset VR_{3001} and VR_{3002} to the center position.
(b) Connect a frequency counter to the cathode of D_{3002} or D_{3003}.
(c) Adjust the core of L_{3007} for the frequency of 62.810.0 MHz.
(d) Now turn the CLAR switch on, and rotate the main knob one click counterclockwise (1 step) ····· displayed "1.999.9" (51.999.9 MHz).
(e) Adjust VR_{3001} and VR_{3002} for a frequency of 62.809.9 MHz.
(f) Repeat the alignment from step (c) to (e) a few times to be sure the proper frequency is obtained.

Tone Burst Circuit

When the T. CALL switch is pressed, the base of Q_{4002} **(2SA733P)** is grounded and a DC voltage is applied to tone burst oscillator Q_{4001} **(TC5082P)** to generate a 1800 Hz tone signal. The tone is superimposed on the transmit signal as long as the switch is held.

ALC Circuit

A portion of the RF signal is coupled through C_{08} to a rectifier circuit consisting of D_{2007} and D_{2008} **(1S188FM)**, producing a DC voltage. The DC voltage is amplified by DC amplifier Q_{1014} **(2SC2603E)** and fed to gate 2 of Q_{1010} to control its gain, thus preventing overdrive. The ALC level is adjusted by VR_{2003} for proper gain at Q_{1010}.

Power Control Circuit

When the HI/LOW switch is set to the low position and the base of Q_{2007} **(2SC2603E)** to a high level, the voltage at the corrector becomes low, thus reducing the voltage at gate 2 of Q_{2019} **(3SK59GR)** and the amplitude of the RF signal.

PLL Circuit

The PLL circuit is composed of a reference crystal oscillator, programmable divider, VCO (voltage controlled oscillator), PLL local mixer, PLL local oscillator, lowpass filter and phase comparator. The PLL produces the local signal for the receiver and transmitter stages, using a synthesis scheme which utilizes 100 Hz steps throughout the range.

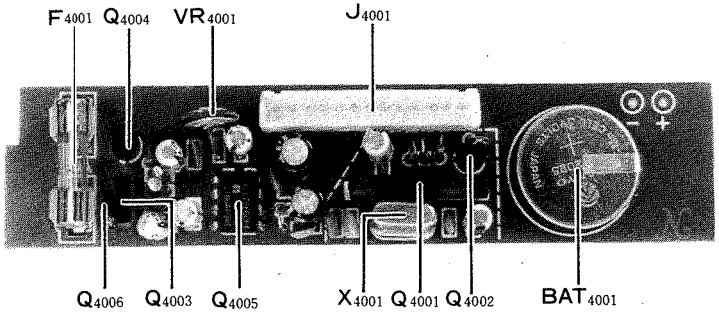
The VCO oscillator, Q_{3001} **(2SK192GR)**, generates a signal at 60.81 – 64.8099 MHz. The oscillator frequency is controlled by varactor diode D_{3001} **(1T25)**, which varies the capacitance of the oscillator tuned circuit in accordance with the control voltage supplied from an active lowpass filter consisting of Q_{3007} **(2SK30AY)**, and Q_{3008} **(2SC945P)**.

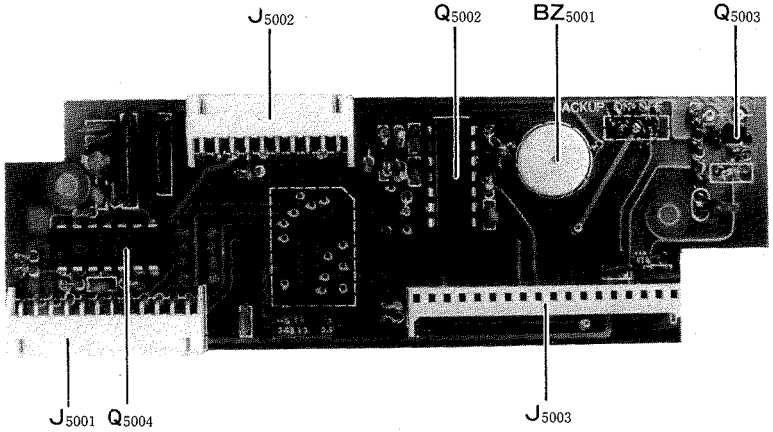
The output signal from Q_{3001} is amplified by buffer Q_{3002} **(3SK73Y)**, and delivered to TX mixer Q_{2017}/Q_{2018} and RX mixer Q_{1002}. A portion of the local signal from Q_{3002} is fed through buffer Q_{3003} **(2SK168D)** to the PLL local mixer, Q_{3004} **(2SC535A)**, where the signal is mixed with a PLL local signal generated by Q_{3009} **(2SC535A)** and multiplied 3 times by Q_{3010} **(2SC535A)**. This local signal varies from 58.81 – 58.8199 MHz as a result of the control voltage from the CONTROL Unit. Thus, a PLL IF frequency of 2.00 – 5.99 MHz is obtained. The frequency varies at the PLL local signal, providing movement in 10 kHz steps.

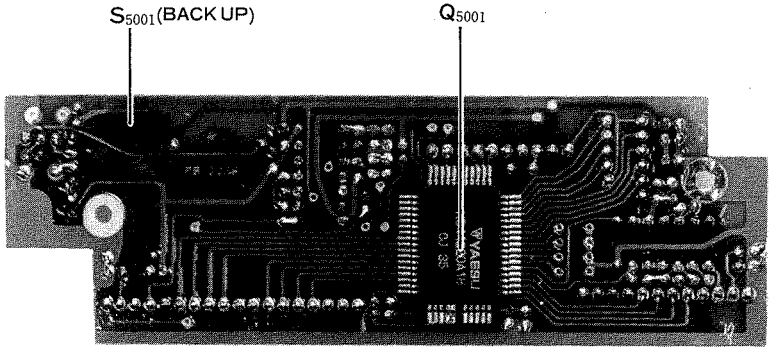
This PLL IF signal is then amplified by Q_{3005} **(2SC535A)**, and fed to Q_{3006} **(μPD2819C)**, where the programmable divider section divides the IF signal by 200 – 599, depending on the data from the 4-bit microprocessor in the CONTROL Unit.

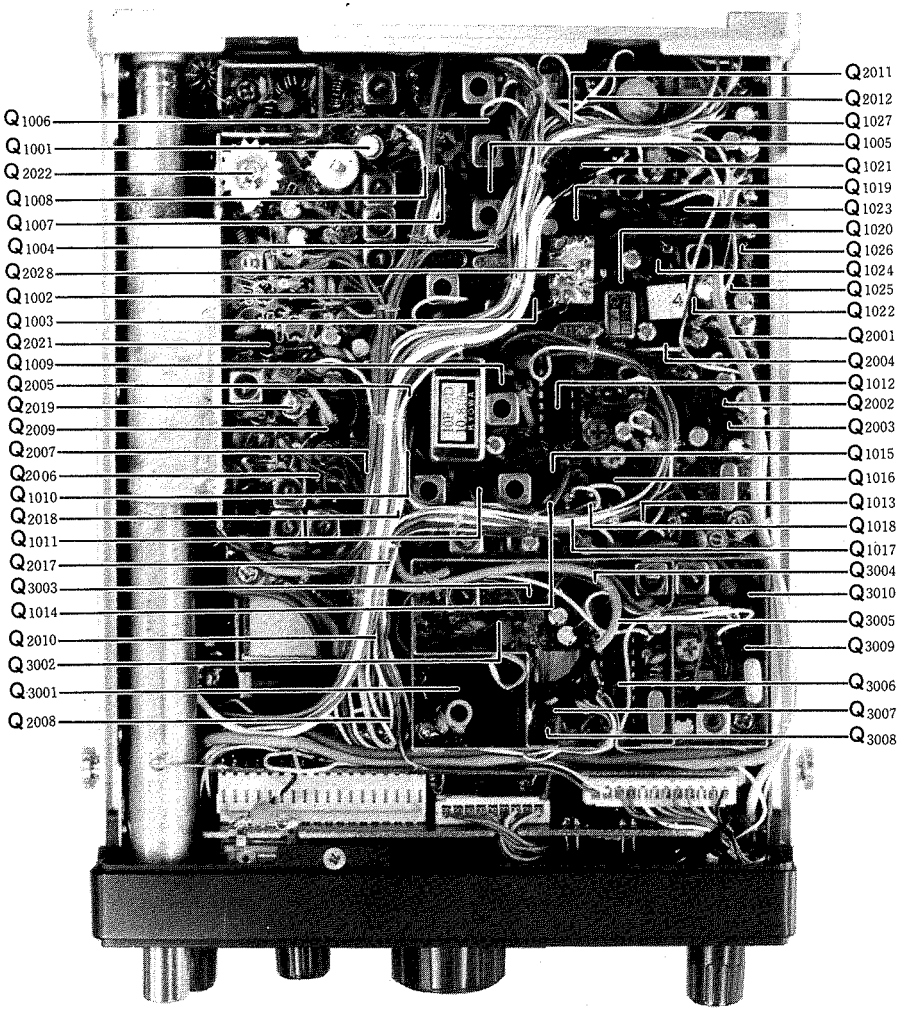
Next, this signal is delivered to the phase comparator section, where the phase of divided IF signal is compared with its reference signal of 10 kHz. This reference signal is generated and divided by the reference oscillator/ reference signal divider section in Q_{3006}. Any difference in phase of the divided PLL IF signal with that of the PLL reference signal is converted into an error-signal with a different bandwidth of pulse. This signal is then fed to active lowpass filters Q_{3007} and Q_{3008}, resulting in a VCO correction voltage.

When the PLL is unlocked, an unlock signal at pin 7 of Q_{3006} drops to a low level, cutting off the bias voltage at Q_{2009} **(2SC2603E)**, and thus turning off Q_{2019} **(3SK59GR)** and Q_{1010} **(3SK73Y)**.









PLL Control Circuit

The PLL Control Unit features a low current drain 4-bit microprocessor chip, Q_{5001} **(HD44820A18)**, which processes data for controlling the operating frequency, UP/DOWN scanning, priority channel, memory selection, etc. The CPU processes input data by means of the main dial or other control switches in accordance with the program stored in a ROM for control of the PLL frequency, indication of the operating frequency, or memory channels on digital display.

MAINTENANCE AND ALIGNMENT

This equipment has been carefully aligned and tested at the factory prior to shipment. If the instrument is not abused, it should not require other than the usual attention given to electronic equipment.

Service or replacement of a major component may require considerable realignment. Under no circumstances, though, should realignment be attempted unless the operation of the transceiver is fully understood, the malfunction has been carefully analyzed, and the fault has definitely been traced to misalignment rather than part failure. Service work must only be performed by experienced personnel using the proper test equipment.

Never align this transceiver without having a 50 ohm dummy load connected to the antenna jack. Troubleshooting using an antenna can result in misleading indications on the test equipment.

EQUIPMENT REQUIRED

1. RF Signal Generator: Hewlett-Packard Model 8640B or equivalent with one volt output at 50 ohms and frequency coverage to 150 MHz.
2. Vacuum Tube Voltmeter (VTVM): Hewlett-Packard Model 410B or equivalent.
3. Dummy Load/Wattmeter: Yaesu YP-150Z or equivalent.
4. AF Signal Generator: Hewlett-Packard Model 200AB or equivalent.
5. IF Sweep Generator: capable of output at 10.81 MHz.
6. RF Sweep Generator: capable of output at 49 – 55 MHz.
7. Oscilloscope: Hewlett-Packard Model 1740A or equivalent.
8. FM Deviation Meter: coverage to 50 – 54 MHz.
9. Precision Frequency Counter: Yaesu Model YC-500E or equivalent with resolution to 0.01 kHz and frequency coverage to 150 MHz.
